DOCUMENTATION OF THE PLANNING SURVEY DATA:  
CROSS-SECTION AND PANEL

James W Albrecht  
June 1990

## 1. Introduction<sup>1</sup>

Since 1975 the Federation of Swedish Industries has collected data from Swedish production units through an annual Planning Survey. These data are available both as unlinked annual cross-sections for the years 1975–86 and as a pooled panel for that period. The cross-sections are available at IUI as APL-workspaces; the pooled panel is available as a SAS-dataset.<sup>2</sup>

My purpose in this paper is to provide a general description and documentation of these data. The Planning Survey data have been used at IUI in connection with the MOSES modeling project, and my primary aim here is to provide documentary background for this project.<sup>3</sup> In addition, I hope to make these data more accessible to other potential users and to provide a general reference source for papers based on the Planning Survey.

My presentation of this material will be straightforward. In the next section I give the basics: how the data are collected, the nature of the respondents, comparability with other data sources, etc. In Section 3 I go through the Planning Survey questionnaire. Then in Section 4 I provide information about how the panel dataset was created. Finally, the appendices provide (i) the basic questionnaires for the cross-sectional data and (ii) a listing of variables for the panel dataset.

## 2. Nature of the Sample

The Planning Survey questionnaires are distributed each year around February 1 to

---

<sup>1</sup>My work on this project and the work of several research assistants have been supported by IUI over a long period. Among those who helped with the programming and data manipulation, Tom Cunningham, Mercedes Grácia-Díez, and Hans-Erik Persson deserve particular thanks. I also thank Ola Virin and Kerstin Wallmark. They were responsible for the actual data collection at the Federation of Swedish Industries, and both provided encouragement and very helpful advice.

<sup>2</sup>Kent-Rune Sjöholm, formerly at the Federation of Swedish Industries and now at IUI, has done similar work with the Planning Survey. He has independently constructed a panel for the period 1980–88. A useful exercise would be to check the two panels for consistency; eventually, the two datasets could be merged.

<sup>3</sup>A general description of the model is given in Eliasson [1989], and Albrecht and Lindberg [1989] explain how the model is initialized using the Planning Survey data.

the largest firms in Swedish manufacturing.<sup>4</sup> Responses come back on a "product line basis." Thus, firms producing a single product or a single line of related products return a single questionnaire, whereas other, more complicated firms may return as many as ten responses. The basic unit of response should be regarded as an establishment or division or "production unit."

Respondents are classified into 5 sectors by the Federation: (i) Raw Materials Processing (R), (ii) Intermediate Goods (INS), (iii) Investment Goods (INV), (iv) Consumption Goods (K), and (v) Building Materials (B). The respondent units comprising a single firm are often classified into different sectors. The Planning Survey sectoral classification conforms with the grouping based on the end use of products suggested by the OECD and is based on the concept of a "product chain." (Raw Materials Processing is an input to Intermediate Goods production which is in turn an input to the production of finished goods.) This end use classification differs from the Standard Industrial Classification used by the Statistics Sweden (SCB) and by the Business Cycle Institute (KI) in connection with their "barometer data."

The coverage of the Planning Survey is quite extensive. Approximately 40–50% of all employment in Swedish manufacturing takes place in establishments covered by the Planning Survey. Significant differences in sectoral coverage reflect the greater importance of larger firms in the Raw Materials Processing and Investment Goods sectors and of smaller firms in Consumption Goods and Building Materials.

There are senses in which Planning Survey respondents are not typical of Swedish manufacturing. One problem is that the survey has a "large firm bias" since firm size is the

---

<sup>4</sup>The Federation of Swedish Industries refers to the surveys in their publications according to the year in which the questionnaires were sent to the respondent firms. Since the first two surveys were sent in December 1975 and December 1976 and the third survey was sent in February 1978, there is no 1977 Planning Survey according to the Federation's dating scheme. I will use the convention of dating the various Planning Surveys according to the year's operations to which they refer. Thus, the survey sent in February 1978 is the 1977 Planning Survey according to my nomenclature.

criterion for inclusion. (All companies with at least 500 employees are included in the survey plus some smaller companies in the Building Materials sectors and a few others of "special interest.") However, the basic units of response are establishments, and some of the production units comprising "large" firms are quite "small." Another problem is that over the sample period (especially during the late 1970's) some operations that might otherwise have been shut down have been taken over by state holding companies. To the extent that these operations are then excluded from the sample, there is a bias in the sample away from failing enterprises. However, I find it difficult to imagine that either of these potential biases is quantitatively very important in a sample that covers close to 50% of total employment in Swedish manufacturing.

### 3. Planning Survey Questionnaire

The Planning Survey questionnaire basically consists of a set of core questions that have been repeated each year plus a small number of extra questions that change from year to year. There are, however, two important caveats to the notion of an unchanging set of core questions. The first is that some core questions were not asked in 1975, the first survey year, and the second is that some core questions have been modified and extended in the later years of the survey.

The core questions cover eight areas:

- a. Employment and Compensation
- b. Sales
- c. Purchases of Raw Materials and Input Goods
- d. Investment Goods
- e. Annual Percentage Change in Production Volume
- f. Capacity Utilization
- g. Orders
- h. Inventories.

Questions for the first four categories are expressed in quantitative terms (number of employees, annual sales in million SEK, etc) and are generally asked both for the survey

year and retrospectively for the preceding year. Questions for the last four categories are expressed in qualitative terms (eg, responses are to be given in percentage ranges) and are not asked retrospectively. All data refer exclusively to the domestic operations of the respondent.

I now summarize the information available for each of these eight core areas. For a complete specification, see Appendix 1.

a. Employment and Compensation

Information is available on the total number of employees and on total compensation (in million SEK, including social fees) both for the year of the survey and retrospectively for the preceding year. Important exceptions to this pattern are (i) no data are available in 1975 on compensation and (ii) total manhours of work are given starting in 1980 in addition to total employment.

My experience has been that some caution must be used in comparing employment figures from two different surveys for the same respondent. The problem is that within firms there may be employees who can plausibly be associated with more than one production unit. However, the survey year and retrospective employment and/or manhour figures within a single survey generally are comparable.

b. Sales

Information is available on total sales (more precisely, total invoicing) in current prices (million SEK) broken down into exports and domestic sales for the year of the survey, retrospectively for the preceding year, and expected (planned) for the year following the survey. Sales to subsidiaries at home and abroad are included.

c. Purchases of Raw Materials and Input Goods

Information is available on raw material and input goods purchases divided into purchases of (i) electricity, (ii) fuels (oil, coal, etc) and (iii) other raw materials and intermediate goods for the year of the survey, retrospectively for the preceding year, and expected (planned) for the year after the survey. Important exceptions are (i) no

information is available for 1975 and (ii) in 1976 and 1977 data are available for total purchases only, rather than for the three components. Starting in 1984, information is also available on "total costs," ie, labor costs plus raw material/input goods costs plus any other costs that fall into neither of the first two categories.

Purchases of raw materials and input goods seem to be systematically understated in these data due to the non-inclusion of the service component (eg, transport services) of such purchases in the survey responses. (A limited corrective based on a supplementary question in the 1981 survey is available. See p 10 below.) Another possible source of measurement error in these data is the existence of unrecorded intra-firm transfers of raw materials and input goods.

d. Investment

Information is available on total investment (million SEK, current prices) divided into expenditures on plant and equipment for the survey year, retrospectively for the preceding year, and expected (planned) for the year following the survey.

e. Production Volume

Information is available on production volume for the survey year as compared with the preceding year and for the year following the survey (expected or planned) as compared with the survey year. The answers are expressed in percent ranges. That is, the possible answers are "approximately unchanged" (change between + or - 5%), "increased by more than x percent (x = 5, 10, 15, 20, 25) or "decreased by more than x percent" (again, x = 5, 10, 15, 20, 25). If an increase or decrease of more than 25% is indicated, then the respondent is asked to provide a precise percentage figure.

f. Capacity Utilization

A spectacular amount of information about capacity utilization is available from the various surveys: eight different capacity utilization questions have been asked at different times over the sample period. Two questions have been asked each year and are

particularly important:<sup>5</sup>

(i) "By what percent could production volume have been increased during the survey year (as compared with the preceding year) had sufficient product demand and supply of labor been available?"

(ii) "By what percent could production volume have been increased during the survey year (as compared with the preceding year) had sufficient product demand existed but with the workforce actually employed?"

The answers to these questions take the form of "It could have been increased by more than x percent (x = 5, 10, 15, 20, 25) or "not at all" (0–5%). If an increase exceeding 25% is indicated, then the respondent is asked to specify a precise percentage figure. Note that to derive utilization figures the actual percent change in production volume needs to be subtracted from the answers to these questions.

The answer to the first question can be used to derive the usual capacity utilization figure, the ratio of actual output to capacity. The answer to the second can be used to derive the ratio of actual output to "potential output conditional on the existing workforce," ie, a measure of labor utilization. The ratio of capacity utilization to labor utilization, ie, the ratio of "potential output conditional on the existing workforce" to capacity, can be interpreted as a measure of the degree to which capital is utilized.

My experience with these data has been very encouraging. First, there seems to be much to be learned from how these utilization figures vary over establishments in the cross section and within establishments over the cycle. (I have made some first steps in this direction in Albrecht [1979].) Second, the obvious inconsistency that one would fear in such data, that the actual expansion in production volume would exceed what respondents

---

<sup>5</sup>These two questions were created with the data needs of MOSES in mind and are referred to as SUM and A21, respectively, in the model. Since 1980 Statistics Sweden has published directly analogous figures on "actual utilization" (FU) and "possible utilization" (MU) on a quarterly basis. The series are related as follows:

$$FU = \frac{1}{1 + SUM} \quad \text{and} \quad MU = \frac{1}{1 + A21}$$

reported as possible, almost never occurs.

Among the other capacity utilization information that is available, two questions that have been asked since 1980 are of particular interest:

(iii) "Could the survey year's output have been produced with a smaller workforce? If so, by how much could the workforce have been reduced as compared with actual employment?"

The answer is again of the form "It could have been reduced by more than x percent" ( $x = 5, 10, 15, 20, 25$ ) with a precise percentage figure called for if a reduction exceeding 25% is indicated. The answer to this question gives a measure of labor redundancy.

(iv) "What increase in employment in the survey year (in percentage terms with actual employment that year as the base) would have been required to reach full capacity?"

The answer to this question, which is of the usual form, gives a measure of "marginal labor requirements."

An interesting exercise (which I haven't yet attempted) would be to use these utilization data to trace out ex post relationships between output and labor input at the establishment level. The accompanying figure shows how this could be done.

Data on actual output and labor input in the survey year provide a base point (A), and the first utilization question (SUM) locates the capacity level of output. The remaining three utilization questions then locate points on the ex post frontier. The second utilization question (A21) locates point B; the third utilization question (labor redundancy) locates point C; and the fourth utilization question (marginal labor requirements) together with knowledge of the level of capacity locates point D. These three points (B, C, and D) along with the origin suffice to sketch out the ex post frontier.

g. Orders

The same three orders questions have been asked in all three survey years. The questions refer to the "order situation" at the end of the survey year as compared with the end of the preceding year. I have no experience with these data.

h. Inventories

Information is available on (i) the stock of product inventories as of the end of the survey year as a percent of survey year sales, (ii) the "normal" ratio of the stock of product inventories to yearly sales, (iii) the stock of raw material and input good inventories as of the end of the survey year as a percent of survey year purchases, and (iv) the "normal" ratio of the stock of raw material and input good inventories to yearly purchases.

Information is available for all years except 1975, and responses are given in percentage range terms.

The inventory data are probably the weakest link in the Planning Survey. A first problem is simply that the inventory measures are rather crude, being based on stock-to-flow ratios that are expressed in broad percentage ranges. A second problem has to do with the prices associated with the inventory stocks. Product inventories can be valued at the current price, at the price that is expected to prevail when the goods are to be sold, or at some other price that is advantageous for tax reasons. Likewise, raw material/input good inventories can be valued at purchase price or current price, a particular problem since raw materials prices, especially fuel prices, moved substantially

over the sample period. Third, no information on inventories of "goods in process" is explicitly asked for in the Planning Survey. Some respondents may include these inventories in their answers to the questions about finished goods inventories; others probably do not. Fourth, although I have no evidence to support this suspicion, there may be incompletely recorded intra-firm transfers of stocks in these data. Finally, even if the data were completely free of measurement error, there still would not be sufficient information to precisely compute changes in inventory stocks from year to year. To compute the change in product inventories using data from one questionnaire, the best one can do is to multiply current sales by the difference between the actual and "normal" ratios of product inventories to sales (divided by 100). This, of course, requires that the stock-to-flow ratio in the preceding year was "normal," an assumption that does not seem consonant with the significant movements in average stock-to-flow ratios over the sample period.

#### Supplementary Questions

Finally, some of the supplementary (non-core) questions are also worth discussing. First, it is possible to use supplementary questions to construct a capital stock time series for some respondents. In the 1979 survey respondents were asked to give the replacement value of their capital stocks broken down into plant and equipment as of the end of 1979, and in both the 1977 and 1986 surveys respondents were asked to give an economic life expectancy (in years) both for buildings and for the most recently installed piece of important machinery. For respondents with complete records we thus have a base capital stock figure from 1979, the means to estimate economic rates of depreciation from the 1977 and/or 1986 surveys<sup>6</sup>, and annual gross investment series. Note, of course, that the possibility of constructing a capital stock series applies only to those units that can be

---

<sup>6</sup>Alternatively, one can use external estimates of depreciation, eg, those given in Södersten and Lindberg [1984].

linked with a respondent from the 1979 survey.<sup>7</sup>

The second set of supplementary questions of particular interest come from the 1981 survey. In that survey respondents were asked to provide information about the service component of total sales and of total raw material/input good purchases. Information about the service component of purchases is particularly important. Respondents were specifically asked to provide a figure for total purchases of services, including transport, and to indicate approximately what fraction of these purchases were reflected in their response to the core questions on raw material and input good purchases. Thus, the responses to the 1981 supplementary questions might be used to derive a correction factor that could then be applied to other years' data on purchases.

#### 4. Creation of the Panel Dataset

The ability to follow individual production units through time, ie, to exploit the panel nature of the data, is an important feature of the Planning Survey. In this section I outline the procedure used to convert the data from a series of unlinked cross sections into a panel.

---

<sup>7</sup>The gross investment series are expressed in current prices. To convert investments to current prices the following implicit price deflators can be used (source: Kerstin Wallmark, 7 May 1984):

	<u>Buildings</u>	<u>Machinery</u>	<u>Total</u>
1973	46.8	47.7	47.5
1974	54.1	55.5	55.1
1975	59.3	63.4	62.1
1976	66.7	69.5	68.7
1977	75.7	76.2	76.1
1978	81.8	85.4	84.4
1979	90.5	92.1	91.7
1980	100.0	100.0	100.0
1981	109.0	108.6	108.7
1982	117.2	124.7	123.3
1983	124.0	141.1	138.1
1984	132.7	145.5	142.8
1985	138.8	150.9	148.3
1986	145.1	158.8	155.4

Note also that I am implicitly assuming in this discussion that investments "enter into" the capital stock in the same year as the investment expenditures are made.

There are three basic steps to this procedure. First, I took data from the cross-sectional APL matrices (these are the "inputs" to the procedure) and re-organized these data into "variable matrices." Second, I "expanded" these variable matrices to take into account those instances in which respondents with the same identification code are not comparable across years. Finally, I converted these expanded variable matrices from APL workspaces to ASCII files (these are the "outputs" from the procedure). I will discuss the re-organization and expansion steps in detail below; the conversion step, however, is straightforward.

### Re-organization of the Data

The APL matrices R75, INS75, ... ,B86 are the input to this first stage. (R75 is the matrix with data from 1975's Raw Material Processing sector's respondents, etc.) Vectors C75, C76, ... , C86 are specified, where C75 gives the columns in the 1975 matrices (ie, R75, INS75, etc) corresponding to the variables of interest, C76 gives the columns in the 1976 matrices corresponding to variables of interest, etc. To carry out the procedures described below, the respondent identification codes (ID's) are required, so 1 (the column corresponding to the respondent ID) is the first element in all the C-vectors. In addition, despite the fact that some information is not available in all survey years (eg, manhour figures are available only from 1980 onwards), the procedure requires that all of the C-vectors have the same number of elements. A solution, explained in the next paragraph, is to set elements of the C-vectors equal to 1 for those cases in which a variable is not included in the survey year in question.<sup>8</sup>

The vectors C75, C76, etc are used to select columns from the basic data matrices. Define X75 as the columns C75 of R75 stacked on top of the columns C75 of INS75, ... , stacked on top of the columns C75 of B75; likewise X76 consists of the columns C76 of R76

---

<sup>8</sup>Example: C75 = 1 2 3 1 1 8 9 10 12 14 15 1 1 1 18 19 20 21 22 23 24 25 26 27 28 29 30 31  
32 33 34 35 36 37 38 39 40 41 1 1 1 1 1 1 42 43 1 1 1 1 1 1 1 1 1 1 1

stacked on top of the columns C76 of INS76, ... , stacked on top of the columns C76 of B76; and so forth through X86. The various X-matrices need to be fixed to take missing variables into account. I adopt  $-99$  as the missing data code. The columns of X75 corresponding to C75 = 1 (excepting the first column, ie, the respondent ID) are set equal to  $-99$ ; likewise, the columns of X76 corresponding to C76 = 1 (excepting the first column) are set equal to  $-99$ ; and so forth through X86. In addition, "check columns" are included in the C-vectors. These "check columns" correspond to "check variables" in the data matrices, ie, to variables indicating whether the respondent answered a particular question. At this point, these columns are used for an "APL compression" and then discarded.<sup>9</sup>

The final step in re-organizing the data is to combine the first columns of X75, X76, ... , X86 into a first variable matrix, the second columns of X75, X76, ... , X86 into a second variable matrix, etc. Using the first variable matrix as an example, this combination essentially results in a matrix the first column of which is the first column of X75, the second column of which is the first column of X76, etc. The only caveat is that not all respondent ID's occur in all years (so the X-matrices have different numbers of rows). To deal with this, define ID as the union of respondent ID's occurring in all years; ie, ID is the union of the first columns of X75, X76, ..., X86. Then define the "selection index" S75 as the position of the ID codes appearing in the 1975 matrices in the vector ID, similarly for selection indices S76, S77, ... , S86. Each variable matrix is of dimension (# of elements in ID) by 12 (ie, the number of years in the cross-sections), and initially each element in each matrix is set to  $-99$ . In the first column of the first variable matrix in the

---

<sup>9</sup>Example: There is a check variable for "Production Volume — percent change in real terms" in each of the data matrices. This variable takes on the value one if the respondent answered the production volume question and the value zero if not. In the 1975 matrices the check variable is found in column 24 and the answer to the production volume question itself is found in column 25. The vector C75 thus includes the entries 24 and 25. These correspond in turn to columns 21 and 22 in X75. If an element of column 21 in X75 equals 0, then the corresponding element of column 22 X75 is set equal to  $-99$ ; if an element of column 21 in X75 equals 1, then the corresponding element of column 22 in X75 is left as is. Once this compression is carried out, column 21 of X75 is discarded.

rows indicated by S75, '99 is then replaced by the first column of X75; in the second column of the first variable matrix in the rows indicated by S76, '99 is replaced by the first column of X76, and so forth.

### Expansion of the Variable Matrices

The output of the above data re-organization is a collection of variable matrices. A row in a particular variable matrix gives a time series of responses on one variable for a single respondent ID. However, the problem with using the Planning Survey data as a time series is that, due to definitional changes, respondents with the same ID codes may not be comparable across years. The solution I have adopted is to treat definitionally different respondents with the same ID codes as separate entities. To do this "index matrices" identifying definitional changes are used. These index matrices are based on coding sheets constructed under Kerstin Wallmark's direction at the Federation of Swedish Industries.

The procedure can be illustrated by example. Consider the "respondent" with the APL identification code 1.01 in the cross-sectional data. (The code 1.01 means that this is the first respondent in Raw Materials Processing, the first sector.) There should be 12 years of data for this respondent; however, the unit is not comparable across the sample period. In particular, the unit was re-defined as of the beginning of 1979 to reflect organizational changes within the parent firm; that is, survey responses for respondent 1.01 before 1979 and after 1979 refer to fundamentally different entities, despite the common identification code. Another re-organization took place at the beginning of 1981. In this case the responses given in the 1981 survey to questions about 1981's operations of course refer to the new, re-defined entity; however, the responses to retrospective questions refer to the entity as it existed in 1980. This same type of re-definition, with a discrepancy between survey year and retrospective responses, also took place at the beginning of 1982 and then again at the beginning of 1983. Finally, in 1984 this "respondent" dropped out of the survey altogether.

Employment from 1975 to 1986 for respondent 1.01 (the first row of the third

variable matrix – note the missing data entries for the years 1984–86) is given by

1872 1812 1571 1476 12607 12728 3851 3336 2206 -99 -99 -99.

To accommodate definitional inconsistencies, this single time series of responses is expanded into five separate time series:

1872 1812 1571 1476 -99 -99 -99 -99 -99 -99 -99 -99  
 -99 -99 -99 -99 12607 12728 -99 -99 -99 -99 -99 -99  
 -99 -99 -99 -99 -99 -99 3851 -99 -99 -99 -99 -99  
 -99 -99 -99 -99 -99 -99 -99 3336 -99 -99 -99 -99  
 -99 -99 -99 -99 -99 -99 -99 -99 2206 -99 -99 -99

To carry out this expansion the index matrix

1.01 1 1 1 1 0 0 0 0 0 0 0 0  
 1.01 0 0 0 0 1 1 0 0 0 0 0 0  
 1.01 0 0 0 0 0 0 1 0 0 0 0 0  
 1.01 0 0 0 0 0 0 0 1 0 0 0 0  
 1.01 0 0 0 0 0 0 0 0 1 0 0 0

is used. If the raw data to be expanded were retrospective employment (or, in general, any lagged variable) a different index matrix would need to be used. For respondent 1.01 this would be

1.01 1 1 1 1 0 0 0 0 0 0 0 0  
 1.01 0 0 0 0 1 1 1 0 0 0 0 0  
 1.01 0 0 0 0 0 0 0 1 0 0 0 0  
 1.01 0 0 0 0 0 0 0 0 1 0 0 0  
 1.01 0 0 0 0 0 0 0 0 0 0 0 0

(Note that the last row of this matrix consists entirely of zeroes. The interpretation is that there is no Planning Survey that gives retrospective information valid for the "fifth respondent" with ID 1.01.)

The index matrices for all respondents taken together (ie, not just respondent 1.01) are denoted by IMAT and ILAG. IMAT, or ILAG in the case of retrospective data, are

used together with any pre-expansion variable matrix in a simple APL program to produce an expanded variable matrix. Although not all respondents are as chaotic as 1.01, this expansion process changes the nature of the data to a considerable degree. The number of "respondents" after expansion is approximately 3 times the number of respondent ID's.

## 5. Conclusion

The panel dataset described above should be used with caution. Despite our best efforts, there are doubtless instances in which noncomparable entities are incorrectly linked through time in the panel. Further, as I indicated in my discussion of the questionnaires, there are some variables that should be regarded with skepticism.

Having expressed these caveats, I nonetheless feel that this is a very rich and interesting dataset. The panel could provide useful information about productivity and technological change; and, as I suggested above, these data could shed considerable light on patterns of capacity utilization over the cycle. In addition, the Planning Survey data could be linked profitably with other datasets available at IUI, eg, with firm-level financial data. In short, this is a dataset that is ripe for exploitation.

## Appendix 1: Cross-section Data — Storage and Coding

The Planning Survey data in cross sections are stored as APL workspaces. There is one workspace per year of data with PD75 containing the 1975 data, PD76 containing the 1976 data, etc. Within each PD workspace the data are stored in 5 matrices. These matrices are identified by a prefix (R = Raw Materials Processing, INS = Intermediate Goods, INV = Investment Goods, K = Consumption Goods, B = Building Materials) and by suffix according to the year. Thus, for example, the workspace PD76 contains the 5 variables (matrices) R76, INS76, INV76, K76, and B76.

Each matrix is of dimension (# of respondents) x (# of variables). With the exception of the 1975 matrices a standard format has been preserved for the first 50 columns of all matrices; that is, in each of the years 1976–86 one can find the respondent ID in column 1, data on employment and wages in columns 2–5, etc. This has been done to make it possible to write standardized programs to analyze data across different years. (The functions used to rearrange the data into this standard format can be found in some of the later PD-workspaces.) Columns 1–50 correspond to what I call the "core variables" in Section 3 of the main text. For columns 51 and beyond what can be found in any given column differs from year-to-year, reflecting additions to the questionnaire and special questions.

Presented below are the codes for each year of data. In reading these codes one finds the expression "check on xx." This variable takes on a value of 1 or 0 according to whether or not the respondent gave an answer to the question called for in column xx; ie, the check is for missing data.

### 1975 Planning Survey

#### 1. ID

#### Number of Employees

2. 1974

3. 1975

4. 1976 (plan)

#### Number of production workers

5. 1974

Service component of sales

What percent of sales in 1986 consisted of services

86. check on 87

87. Services sold in connection with goods (installation, maintenance)

88. check on 89

89. Services sold separately (technical services, data services)

## 1986 Planning Survey, continued

90. check on 91

91. Total services

Economic life length of capital equipment

92. check on 93

93. Expected economic life length of the most recently installed piece of important equipment (in years).

94. check on 95

95. Expected economic life length of recently constructed plant (years)

Depreciation

Which write-off method do you regard as the economically best way to depreciate machines?

96. check on 97-99.

97. straight-line

98. accelerated

99. other

Second-hand market

Is there a functioning second-hand market for your more important types of machines?

100. check on 101-103

101. Not at all

102. To some degree

103. Very much so.

## Appendix 2: SAS Panel Dataset

The dataset consists of 46 SAS variables. Four of these variables are "index variables" — the observations are indexed by establishment, by year, by industry, and by their APL codes in the cross-sectional data.; 31 variables come from the core part of the Planning Survey ("core variables"); and 11 variables contain information from the supplementary part of the Planning Survey ("supplementary variables"). Missing data are coded as -99.

### A. Index Variables

I: Establishment index  
Takes on the values 1, 2,...,xx  
T: Year index  
Takes on the values 75, 76,...,86  
IND: Industry code  
Takes on the values 1.1, 1.2,...,5 as shown below.

#### 1. Raw Materials Processing

1.1 Iron and Steel  
1.2 Non-Ferrous Metals  
1.3 Saw Works  
1.4 Pulp

#### 2. Intermediate Goods

2.1 Chemicals  
2.2 Metal Working  
2.3 Paper

#### 3. Investment Goods

3.1 Machinery  
3.2 Electronics  
3.3 Office Furniture  
3.4 Shipbuilding

#### 4. Consumption Goods

4.1 Food-Tobacco-Beverages  
4.2 Textiles-Shoes-Leather  
4.3 Pharmaceuticals  
4.4 Consumer Durables  
4.5 Graphics  
4.6 Furniture

#### 5. Building Materials

APL: APL code in cross-sectional data  
Takes on the values 1.01,..etc

## B. Core Variables

These are the variables that are available for all years (with some exceptions in 1975).

LLAG: Number of Employees in T-1

L: Number of Employees in T

\*\*\*\*The following variables are in current prices, million SEK\*\*\*\*

WLAG: Total Wage Bill (including social fees) in T-1

W: Total Wage Bill (including social fees) in T

S1LAG: Sales Abroad (including to affiliates) in T-1

S1: Sales Abroad (including to affiliates) in T

S1EXP: Sales Abroad (including to affiliates) in T+1 (expected)

S2LAG: Sales Domestic (including to affiliates) in T-1

S2: Sales Domestic (including to affiliates) in T

S2LAG: Sales Domestic (including to affiliates) in T+1 (exp)

RLAG: Raw Material and Input Good Purchases in T-1

R: Raw Material and Input Good Purchases in T

REXP: Raw Material and Input Good Purchases in T+1 (expected)

I1LAG: Investment Expenditures, Plant and Building (including air conditioning, sanitation, etc) in T-1

I1: Investment Expenditures, Plant and Building (including air conditioning, sanitation, etc) in T

I1EXP: Investment Expenditures, Plant and Building (including air conditioning, sanitation, etc) in T+1 (expected)

I2LAG: Investment Expenditures, Machinery and Equipment, (including transport equipment) in T-1

I2: Investment Expenditures, Machinery and Equipment, (including transport equipment) in T

I2EXP: Investment Expenditures, Machinery and Equipment, (including transport equipment) in T+1 (expected)

\*\*\*\*Percents Expressed in Whole Numbers\*\*\*\*

DQ: Production Volume — Percent Change from T-1 to T

DQEXP: Production Volume — Percent Change from T to T+1 (exp)

\*\*\*Note: To use A21 and SUM to compute utilization rates, one needs first to subtract off DQ\*\*\*\*

SUM: "By what percent could year T's production volume have increased (as compared with T-1), assuming labor supply and product demand imposed no constraint?"

A21: "By what percent could year T's production volume have increased (as compared with T-1), assuming product demand available but with the existing labor force?"

DC: "By what percent can year T+1's production volume increase (as compared with T), given already decided—upon capacity increases and assuming labor supply and product demand impose no restraint?"

DORDER: Percent change in orders from T-1 to T

COVER1: Percent of planned production in T+1 covered by existing orders

COVER2: Order coverage for T+1 (-1 = less than normal; 0 = normal; 1 = greater than normal)

RSTO:	Raw materials inventories as of the end of year T as a percent of total purchases of raw materials in T (including fuels)
NORMRS:	Normal ratio of raw materials inventories to purchases
STO:	Product inventories as of end of year T as a percent of total sales in year T
NORMST:	Normal ratio of product inventories to sales volume

### C. Supplementary Variables

COST:	Total Costs (labor costs + raw material/input goods costs + "other costs") (available from 1984–86)
ELAG:	Electricity Costs in T–1 (including internally generated) (available from 1978–86)
E:	Electricity Costs in T (including internally generated) (available from 1978–86)
FLAG:	Fuel costs in T–1 (coal, oil, etc) (available from 1978–86)
F :	Fuel costs in T (coal, oil, etc) (available from 1978–86)
HLAG:	Total manhours (in 1000's) in T–1 (available from 1980–86)
H:	Total manhours (in 1000's) in T (available from 1980–86)
K1:	Replacement value of capital stock (building and plant) as of 31 December 1979
K2:	Replacement value of capital stock (machinery and equipment) as of 31 December 1979
MLR:	"What increase in employment in year T (compared with actual employment that year) would have been required to reach full capacity?" (available from 1980–86)
RED:	"Could year T's production level have been achieved with less employment? If so, by how much less as compared with actual employment in T (in percentage terms)?" (available from 1980–86)
